

Decay studies of proton-rich nuclei near ^{100}Sn with AIDA at RIKEN

Monday, July 22, 2024 2:40 PM (20 minutes)

The neutron-deficient region of the nuclear chart in the vicinity of the doubly magic nucleus ^{100}Sn is of great interest in nuclear structure physics. Measurement of the decay properties of the spherical $N \approx Z \approx 50$ nuclei in this region acts as a direct test of the shell model around the major shell closures, and can assist in establishing the location of the proton drip-line. An experiment at the Radioactive Ion Beam Factory (RIBF) facility at RIKEN, Japan was carried out to perform these measurements with the state-of-the-art Advanced Implantation Detector Array (AIDA) silicon detection system, the first use of this system on proton-rich nuclei at this facility. This talk presents a discussion of the experiment and the analysis of data collected with AIDA.

Support for this project from the Science and Technology Facilities Council (STFC), UK Research and Innovation is acknowledged.

Presenter: APPLETON, Corrigan (Lawrence Berkeley National Laboratory)

Session Classification: Facilities, Campaigns, and Devices
